PROVENANCE FOR INTERNET ART

Using the W3C PROV data model

Abstract – When a scholar, curator or archivist is researching an artwork, they need provenance, an essential piece of information that can help them evaluate as to whether a source can be trusted. This paper will investigate how to express the provenance of Internet art as linked data. One of the standards that has emerged to describe the provenance of digital data is the W3C PROV. It provides a model which facilitates description of the entities, agents and processes involved in producing data. This generic model has proven to be applicable in various contexts, including the cultural heritage domain [1, 2]. However, its potential to describe the provenance of Internet art is not yet fully explored [3]. This paper demonstrates how the PROV model can be used to describe the provenance of Internet art by applying it to a case study from Rhizome’s ArtBase, an online archive dedicated to preserving works of Internet art. This paper is aimed at digital art conservators, digital curators, Web archivists and art historians.

Keywords – Provenance, Internet art, Rhizome, W3C PROV, linked data

Conference Topics - Collaboration: a Necessity, an Opportunity or a Luxury; Designing and Delivering Sustainable Digital Preservation

I. INTRODUCTION

During the nineties, shortly after the wider introduction of the World Wide Web, artists started to create artworks within this online environment. These digital artworks were (and some of them still are) embedded within the Web. At the time of writing, there is not a definite name for these artworks. Various terms can be found in the literature, including “Internet art”, “Net(work)-based art”, “Web art” and “net art”. Throughout this paper we will use the term “Internet art”. Characteristic for Internet art is that the work evolves over time, often into various instantiations (or versions). In Rhizome’s ArtBase, instantiations are referred to as “variants”, a term developed by Dragan Espenschied, which we will also adopt in this paper.

Over the last 20 years, Internet artworks have increasingly entered museum collections and archives, and the study of these artworks is becoming part of art historical research. This brings new complexities. For instance, historians are advised to proceed with caution when studying an Internet artwork as there is limited provenance information available (or made accessible), which is essential for critically evaluating the reliability of the source as evidence. Normally, researching the provenance of artworks includes an object study, going through resources about the artist (e.g. catalogues raisonnés) and other owners (e.g. auction results and exhibition catalogues). Not all of this is available, and sometimes it is not even applicable for Internet artworks.

In this paper we will demonstrate a new approach to describe the provenance of Internet art by testing the application of the PROV Data Model (PROV–DM). Instead of a history of ownership, PROV–DM describes “the people, institutions, entities, and activities, involved in producing, influencing, or delivering a piece of data or a thing” [4]. It was developed as part of a family of documents published by the Provenance Working Group at W3C, which also include an OWL2 ontology (PROV–O), developed for mapping PROV–DM to RDF.¹

PROV–DM offers several advantages. Most importantly, this model makes it possible to give an overview of the lifecycle of an artwork. The PROV model does not only capture the creation of the artwork, but also how people contribute to or influence the work over time. Furthermore, PROV–DM can capture the different variants of a single artwork, even when these are preserved across

DOI: 10.1145/nnnnnnn.nnnnnnn
various institutions. A single Internet artwork can be included in multiple (museum) collections, (Web) archives, whilst being part of the live Web. At the moment, there is not a single way of describing provenance adopted by all. Another advantage of the PROV-DM is that it functions as a provenance interchange model between heterogeneous systems. This offers the opportunity to exchange provenance information across (data) collections held by different memory institutions.

Our key objective in this paper is to provide an example of how provenance can be expressed for an Internet artwork, and demonstrate a practical approach to using PROV-DM. Section II outlines the methods we used, followed by section III which investigates how PROV-DM can be applied to an Internet artwork, including how it can be implemented in a linked data knowledge management system. Section IV discusses key issues that came up in the modelling and implementation processes, some of which may also require future research. Finally, section V concludes the paper.

II. METHODS AND METHODOLOGY

A. Application of the PROV model

For this paper, we applied the PROV model to Internet art in three steps: First, we reconstructed the lifecycle of the artwork, based on archival research and by using historical methods. Next, we translated this information in a PROV-DM application that illustrated the key components of provenance we considered necessary (section III.B). In the final step, we used PROV-O to map PROV-DM to RDF in Rhizome’s Wikibase (section III.C).

PROV-DM consists of six components, of which we tested three for this paper (the PROV core structures) [4]. Component 1 (C1) describes the "entities” and “activities”. An entity can be a variant of the artwork, and/or physical, digital or conceptual elements of the artwork. An activity is something that affects an entity within a certain time period. Component 2 (C2) describes “derivations”. In our case this means how one variant of an artwork derives from or relates to another. Component 3 (C3) refers to agents and their responsibilities. An agent can be a person, as well as an organization or a piece of software. Using these components – C1, 2 and 3 – it becomes possible to pose and answer questions such as: "Who [agent] did something [activity] to this variant of this artwork [entity]?”; or: “How does this variant relate to other variant(s) [derivation]?”; etc.

B. Interdisciplinary collaboration

All findings presented in this paper are a result of interdisciplinary collaboration. At each stage, we made prototypes, which we reflected on and discussed, bringing our own areas of expertise. Through iteration, the outcomes were further refined. We adopted a practice-based research method, in which collaborative prototyping is a mode of enquiry [5].

C. Case study approach

Although this paper focuses on a single case study, we prepared models for various Internet artworks. The results were compared to further understand PROV-DM and, in particular, how to model the relationships between entities, agents and activities. Based on these initial tests, one artwork was selected and studied in more detail. All artworks tested are part of the ArtBase, one of the largest archives of Internet art that is accessible online since 1999. Maintained by Rhizome (USA), the ArtBase is also one of the few online art archives to support a functional linked data infrastructure, which can facilitate the implementation of a linked data provenance model.

The case study that is discussed in this paper is “untitled[scrollbars]” by artist Jan Robert Leegte. This case study was selected for a number of reasons. First, the ArtBase features several variants of the artwork, which offered the opportunity to model how the artwork evolved over time. Additionally, the record for this particular artwork features more detailed information about the accession and preservation of the work, compared to other records in the archive. Lastly, unlike many other examples of Internet art, this artwork does not contain external media or data sources dependent on third-party services. Such media and services would require additional provenance research outside the scope of this initial study.

III. CASE STUDY

A. “untitled[scrollbars]”

Figure 1. Jan Robert Leegte, “untitled[scrollbars]” (2000), web project, source: Rhizome ArtBase (Q2508).

The artist Jan Robert Leegte lives and works in Amsterdam, The Netherlands. He is part of a generation of artists, also known as the net art movement, who have been making art on the Web since the nineties. His early works rebuild basic,
interactive elements of the (classic) Windows interface, such as buttons, window frames or scrollbars. The artwork “untitled[scrollbars]” was published online in 2000. Over time, the title of the artwork has changed from “untitled” to “untitled[scrollbars]” and “scrollbarcomposition”, additionally the artwork can be encountered at various URLs. It can also be understood as part of a larger corpus of works, including a physical installation with the same title, consisting of a wooden structure and a projection of a Windows 98 or a Mac Aqua version of the scrollbar (2005, 2011). In 2001, “untitled[scrollbars]” was accessioned by the ArtBase, where an archived variant (in HTML), as well as a WARC (Web ARCHived) file are preserved.

B. Application of PROV–DM

We developed a data model for the provenance of “untitled[scrollbars]” [Appendix A]. In this model, we applied three views on provenance that PROV supports: “data flow view”, “responsibility view” and “process flow view”, and we used the associated classes and properties from PROV–O [4].

We began our modelling process with the “data flow view”, which shows how one variant of an artwork derives from another. First, we identified all variants of the artwork that can be found in the ArtBase. These include two archived variants – in the custody of Rhizome, and two further URL’s that pointed outside the ArtBase. In the provenance information we had available, it was not possible to find the derivation relationships for all of the variants. Building upon the data structure already in use in the ArtBase, we added one additional entity in our data model to represent the “artwork” as a general concept. PROV–DM provides support for modelling relationships between a general concept of an entity (the artwork) and its specific instantiations (the variants) with the properties prov:alternateOf and prov:specializationOf [4]. An entity that is a “specialization” of another shares all aspects of the latter. On the other hand, two “alternate” entities share some aspects of the same thing, but may also differ and may or may not overlap in time [4]. Since the way an Internet artwork evolves over time is unpredictable and variants can differ substantially from one another, we found the latter, broader term more suitable in our case study.

Next we modelled the “responsibility view”, which involves assigning the agents responsible for different events in the artwork’s lifecycle. We distinguished between the concepts of “attribution” and “association”. In our model, we use attribution specifically in relation to the artist/creator of the work, whereas we use association to refer to any other contributors or the archivist/archival institution. All variants of “untitled[scrollbars]” in our case study can be attributed to the same artist – Jan Robert Leegte. Therefore, we assigned the attribution property to the entity representing the general concept of the artwork. Thus, it can be inferred for all variants. In contrast, we assigned association agents to each specific variant. We found this to be a useful way of documenting custodial care, i.e. whether the variant is in the care of an artist (prov:wasAssociatedWith :artist) or an archive (prov:wasAssociatedWith :archivist → :archivalOrganisation). Association can be related to entities, or activities. In the latter case, it becomes part of the “process flow view”.

In the “process flow view”, we refined our data model by including “generation” activities (i.e. creation), and appended dates and locations. The generation activities in our case study include “Cloning” and “Webrecorder capture”. Cloning refers to creating a file directory copy of the artwork from the artist’s server to Rhizome’s server. Webrecorder capture refers to creating a WARC (Web ARCHive) of the artwork, using Rhizome’s tool Webrecorder. This activity is subject to the decisions of an archivist performing the capture. In order to document this agent’s influence, we assign the association directly to the activity, rather than the variant. Furthermore, this association can be qualified (modelled as a prov:qualifiedAssociation in PROV–O) by additional properties, e.g. adding a “plan” to the activity, for example the archival instructions used during capture. A generation activity can also be qualified (modelled as a prov:qualifiedGeneration) by dates and times with the prov:AtTime property. When no particular activity of generation is assigned to a variant, the variant can still be dated using the prov:generatedAtTime property. Lastly, in addition to multiple times and activities of generation, the variants in our case study had different URL addresses. We used the prov:atLocation property to assign URL locations to each variant.

C. Implementation in Rhizome’s Wikibase

1. Wikibase and Wikidata

Rhizome is one of the first cultural heritage organisations to use Wikibase as a knowledge management system for its archive, the ArtBase [6]. Wikibase is the open source software environment built to run Wikidata. Wikidata is a knowledge base of public domain structured data maintained by the (non-profit) Wikimedia

The artwork being created, presented or preserved, rather than tracking file system activities related to individual files such as checksum creation, etc.

2 Please note that the level of abstraction in this model is higher compared to other digital preservation standards, such as PREMIS. We are modelling activities that lead to a variant of
foundation (WMF). Originally, the Wikimedia software infrastructure was not designed as a linked data system. Linked data capabilities were added later to serve the community needs for interoperability with existing linked data sets [7].

Currently, Wikidata’s knowledge base follows RDF principles, and is organised in subject-predicate-object triples. These translate to item-property-value statements in terms of Wikidata syntax (e.g. artwork [item] → attributed to [property] → artist name [value]) [7]. Statements can have bibliographic references, too. This is how PROV-O is currently being used in the RDF data that can be exported from Wikidata. The prov:wasDerivedFrom property is used to link a bibliographic source to a particular statement. This limited application of PROV is insufficient in the case of Internet artworks and additional concepts and properties are needed.

Crucially for our use case, Wikibase can be deployed as a separate stand-alone instance, independent from Wikidata. While it still follows the RDF data modelling conventions of Wikidata, an independent Wikibase installation requires a custom configuration of concepts and properties [6]. This is how Rhizome’s Wikibase can adopt some PROV-DM concepts and PROV-O properties. Derivation and attribution, for instance, can easily be modelled as item-property-value triples. Owing to its legacy ties to Wikimedia software, Wikibase is very good at representing data related to things (e.g. Wikipedia pages), which become “items” in its RDF statements. The concept of the item can be mapped to the PROV-DM concept of an entity. The concept of the qualified activity (or process) from PROV-O, however, is more challenging to represent in Wikibase.

2. Mapping concepts and properties

The possibility to map concepts across different concept schemas is an integral part of the design of linked data. The SKOS (Simple Knowledge Organisation System) data model was developed specifically to facilitate such linking across knowledge organization systems on the Web.3 The SKOS mapping property (i.e. skos:exactMatch) is already being used in Wikidata as a way to match a concept from one standard schema to another.4 Using skos:exactMatch, it is also possible to link properties and concepts from Rhizome’s Wikibase to corresponding PROV-O properties and concepts [Table I].

The “data flow” and “responsibility views” can be fully represented in Wikibase via such mapping. The “process flow” view presents challenges with regards to the qualified relations, which in order to be represented in Wikibase may have to be broken down and simplified [Appendix B]5. In some cases, it is possible to model PROV qualified processes with Wikibase “qualifiers” – these are sub-properties which can be added to statements, providing additional detail such as time periods, locations, etc. Qualifiers add flexibility to data modelling in Wikibase, however, this flexibility can also make querying more difficult because if a user would need to know the exact structure of the data model in order to make a meaningful query [7].

While this may be considered a limitation of the system, it also provides an opportunity to model provenance data in statements that are both easier to present to end-users accessing the data via a graphical user interface (GUI), as well as easier to query by users who want to find the provenance of artworks without being experts in the particular data model used in the ArtBase.

IV. DISCUSSION

A. Linking variants to a general concept

To gain insights into the provenance of an artwork, it is important that a query can retrieve all variants of the work. While a general concept is not required in PROV-DM, we used prov:alternateOf to connect all variants of the artwork to a general concept. This strategy is compatible with other cultural heritage and bibliographic semantic models, such as CIDOC–CRM and FRBRoo, where our concept of the “artwork” is equivalent to E28 Conceptual object (CIDOC) or F1Work (FRBR), and “variant” is equivalent to E73 Information Object (CIDOC) or F2

3 See the current record for “untitled[scrollbars]” in the ArtBase with partial PROV implementation: https://staging.catalog.rhizome.org/wiki/Item:Q2508

https://www.w3.org/TR/skos-reference/ https://www.wikidata.org/wiki/Property_talk:P2888
Expression (FRBF).\textsuperscript{6,7} This compatibility offers the potential for information exchange between different cultural heritage collections.

B. Modelling historical gaps

Although closing knowledge gaps within the provenance of an artwork remains the goal, a ‘complete’ story can rarely be established. Considering the complexity of historical data, it is important to find ways to model gaps, inconsistencies and/or errors. PROV–DM offers the opportunity to state partial or incomplete provenance about an entity. For example, in the provenance for “untitled[scrollbars]” we added a date towards the general concept of the artwork (2000), but not to the variant that entered the ArtBase. This indicates that it is known that the artwork was created in 2000, but it is not precisely known when the particular variant accessioned by the ArtBase was created. Not only is it possible to leave out unknown information, PROV–DM also allows modelling in increasing levels of detail. For example, the provenance for “untitled[scrollbars]” indicates that the agent who accessioned the artwork is an archivist (their role). When provenance research reveals additional information, it is possible to further refine the provenance by adding, for example, a person’s name (taking into consideration that their identity can be revealed) or more details about their actions (e.g. archival plans, etc).

C. Accessing provenance data

The considerations for implementing PROV–DM in a linked data art archive extend to how it will be accessed by end-users. Despite its limitations with regards to expressing qualified processes, the Wikibase system does provide a GUI, where the complexity of a graph database is made intelligible to end users [6]. While full integration of the PROV-O into Wikidata RDF expressions is not yet possible, if equivalent properties and concepts are accurately mapped, users will have the ability to query the ArtBase for PROV statements using a query service, such as the Wikidata Query Service. The formal terms for running federated queries across knowledge bases remain a matter of debate within the Wikidata community. A universal adoption of a standard mapping notation such as skos:exactMatch would improve the usability of the query service, particularly for users who would like to use it via a GUI. Until this adoption is implemented, users will need to first express the desired mapping in SPARQL and then formulate the particular query of interest.

V. CONCLUSION

In this paper we have presented a novel approach to expressing provenance for Internet art using PROV–DM. Its key advantage is that it facilitates the description of the lifecycle of the artwork more precisely, including any changes that were made over time and who was responsible for them. Additionally, it offers the opportunity to provide an overview of all the variants of an artwork, even when they are included in different collections and archives.

In future work, we will test PROV–DM against further case studies to include other types of provenance entities, agents and relationships. Currently the Wiki data model does not support full integration of PROV–DM in its RDF data expressions. This issue can be resolved with further development work on provenance within Wikibase. For the time being, we have demonstrated alternative ways of working with PROV-O and PROV–DM in the ArtBase. We see future collaborations between digital preservation professionals, historians and the Wikimedia community as a key route to the wider adoption of PROV as a standard practice for preserving and presenting provenance of Internet art as linked data on the Web.

ACKNOWLEDGMENT

The authors would like to thank the following colleagues for their support and contributions to this research: Annet Dekker, Anisa Hawes, Katherine Thornton, Rhizome’s Digital Preservation team, and Wikidata’s development team at Wikimedia Deutschland. Lozana Rossenova would like to acknowledge that her PhD research is funded by AHRC (UK) with additional support from Rhizome.
